Coral reefs are found in a relative restricted area due to the biology of the corals and the bacteria that live within them. Their distribution is generally limited to within 30 degrees either side of the equator where the water is warmest. For a coral reefs to exist, the water temperature must be above 18°C and the depth less than 100m.

The highly significant environmental differences between the reef margins on the windward and leeward sides of reefs, already noted elsewhere, e.g. in East Indian reefs (Umbgrove, 1947)and at Low Isles and reefs of the Great Barrier series, have been described in great detail for these atolls, notably by Tracey et al. (1948), Mu& and Sargent (1964) and Wells (1954,1957).

The coral reefs are of three kinds, depending on how they are formed. 1. Fringing reefs: Coral reefs lying close to the shores of some volcanic island or part of some continent are termed fringing reefs. A fringing reef may extend out to a distance of a quarter mile from the shore with the most active zone of the coral growth facing the sea.
